

# Chemical Formulas & Naming Simple Compounds

Lecture 8

# Chemical formulas

The formula for a compound indicates the combination of the elements that compose it.

- Can be as simple as that for one or two atoms like H or H<sub>2</sub>
- Or more complicated looking, if a molecule is larger like cholesterol: C<sub>27</sub>H<sub>46</sub>O.
- The subscripted numbers tell you how many atoms of that element a molecule of that substance has.

Cholesterol has 27 atoms of carbon, 46 of hydrogen and 1 oxygen atom in a molecule.

# Oxidation Numbers

These are given on the periodic table, they can be positive, negative or zero.

They are the electric charges atoms commonly have when combined.

Atoms have a common oxidation number, but it can differ.

When not using a periodic table this would be given information, written with a superscript on the right side seen in these examples:  $\text{H}^+$ ,  $\text{Al}^{3+}$ ,  $\text{O}^{2-}$ ,  $\text{Cl}^-$ . The number 1 is never written.

Oxidation numbers order the symbols as you write the formula.

They also create the ratio of atoms bonded.

# Binary Compounds

- Atoms with negative oxidation numbers combine with atoms with positive oxidative numbers in such a way to cancel the charges. (algebraic sum=0)

- Example:

$\text{Na}^+$  and  $\text{F}^-$  combine and create  $\text{NaF}$

Generally, the item with a positive oxidative number is written first-not always.

How would you combine  $\text{Ca}^{2+}$  and  $\text{O}^{2-}$  ?

**Answer: CaO**

- How would you combine  $\text{Ca}^{2+}$  and  $\text{F}^-$  ?

**Answer:  $\text{CaF}_2$**

How would you combine the following:

$\text{Li}^+$  and  $\text{O}^{2-}$

$\text{Fe}^{3+}$  and  $\text{S}^{2-}$

$\text{Al}^{3+}$  and  $\text{F}^-$

$\text{H}^+$  and  $\text{N}^{3-}$

# Answers

Li<sup>+</sup> and O<sup>2-</sup>

Fe<sup>3+</sup> and S<sup>2-</sup>

$\text{Fe}_2\text{S}_3$  (here you need a number common to 2 and 3 which is 6:  $3+ \times 2 = 6+$  and  $2- \times 3 = 6-$  the sixes cancel out.)

Al<sup>3+</sup> and F<sup>-</sup>

H<sup>+</sup> and N<sup>3-</sup>

$\text{H}_3\text{N}$  *but we actually write it*  $\text{NH}_3$  (*ammonia*)

# Naming Binary compounds:

- Binary compounds are named starting with the element with the positive oxidation number first.
- Followed by the element with the negative oxidation number.
- You use the first element's name and add -ide to the second element's name.
- Example:             $\text{Li}_2\text{O}$     Lithium Oxide  
                              $\text{Fe}_2\text{S}_3$     Iron Sulfide

# Names of some elements with negative oxidative numbers:

H<sup>-</sup> hydride

Br<sup>-</sup> bromide

I<sup>-</sup> iodide

Cl<sup>-</sup> chloride

F<sup>-</sup> fluoride (yes it is spelled uo)

S<sup>2-</sup> sulfide

O<sup>2-</sup> oxide

P<sup>3-</sup> phosphide

N<sup>3-</sup> nitride

C<sup>4-</sup> carbide

# Roman numerals in the name

- Many elements have more than 1 positive oxidation number and will combine in multiple ways with the same element.

For example :  $\text{FeO}$  and  $\text{Fe}_2\text{O}_3$

- Roman numerals in the written name in parentheses indicate which oxidation state an element is in, since they can vary.

Iron (II) oxide tells you to use  $\text{Fe}^{2+}$

iron (III) oxide tells you to use  $\text{Fe}^{3+}$

Name these :

- Mg F
- KH
- NiI<sub>2</sub>

Write the formula for these:

Copper (II) sulfide

Iron (III) bromide

# Answers

- Mg F                      magnesium fluoride
- KH                         potassium hydride
- NiI<sub>2</sub>                        nickel (II) iodide

Copper (II) sulfide

CuS

Iron (III) bromide

FeBr<sub>3</sub>

# Polyatomic ions

A group of atoms can have an oxidation number too. Some common examples:

Carbonate	$\text{CO}_3^{2-}$	all 4 atoms have a net -2 charge
Hydroxide	$\text{OH}^-$	both atoms have a net negative charge
Nitrate	$\text{NO}_3^-$	all 4 atoms have a net negative charge
Ammonium	$\text{NH}_4^+$	all 5 atoms have a net positive charge

# Polyatomic ions help with naming complex molecules

- Follow the same rules as before:

Write the formula for sodium phosphate:

Phosphate has a negative 3 charge

Sodium has a positive 1 charge

(You need 3 sodium atoms to match the -3 charge of phosphate)

sodium phosphate's formula is written so:

# Try these

- How would you write calcium sulfate?

Calcium is  $\text{Ca}^+$

Sulfate is  $\text{SO}_4^-$

- How would you write ammonium carbonate ?

Carbonate is  $\text{CO}_3^{2-}$

Ammonium is  $\text{NH}_4^+$

# Answers

## **calcium sulfate:**

Calcium is  $\text{Ca}^{+}$

Sulfate is  $\text{SO}_4^{-}$

The charges are equal drop them and put the two together:  $\text{CaSO}_4$

## **ammonium carbonate:**

Carbonate is  $\text{CO}_3^{2-}$

Ammonium is  $\text{NH}_4^{+}$

You need 2 of the ammonium ion to cancel carbonates -2 charge:  $(\text{NH}_4)_2\text{CO}_3$

# Tip of the ice berg

- This is a good start, as molecules get larger and more complex you would need additional rules and information about how to name a compound.
- There are multiple ways that most chemicals can be named.
